## Overview

The most recent trap collection was on August 11, 2015. The 1813 mosquitoes trapped (approximately 181 per trap) is at the 63 percentile of all historical trappings.

As predicted, the number of weekly trapped mosquitoes has begun to rise. Recent precipitation suggests a continued rise in the mosquito population through the end of the month.

## Historical perspective

Numbers so far this summer have been relatively low. However, it's worth noting that peak mosquito population is usually reached later in the summer.

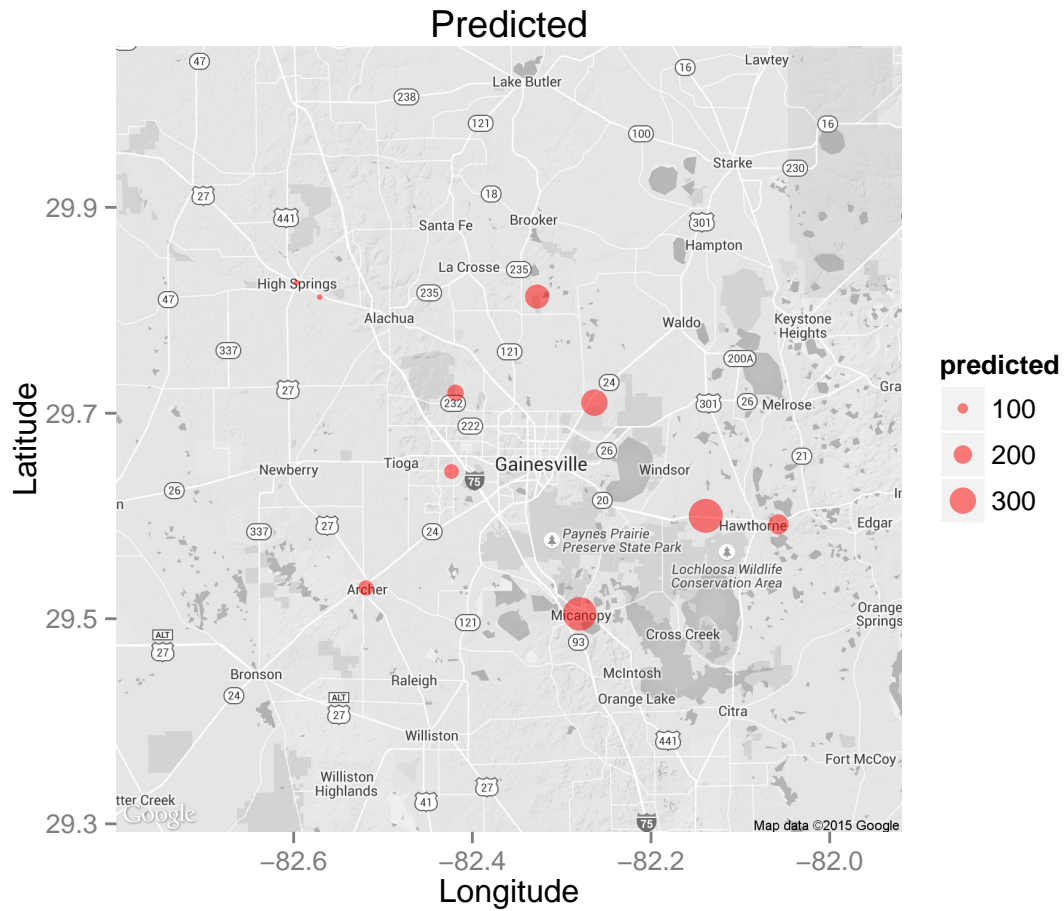

# Disease details

Vectors of diseases of concern appear relatively evenly distributed throughout the county.

## Forecast

Over the next two weeks, we predict the mosquito population to grow slightly, with the greatest growth occurring in the south of the county (towards Micanopy) and east (Hawthorne area).

## Model details

The forecast model has undergone several improvements since last year. The inputs have been substantially expanded (now taking into account humidity, precipitation, wind speed, temperature and its fluctuations), and the model has been improved (in lieu of linear regression, the predictive model now employs ensemble machine learning methods).

The model is cross-validated and backtesting confirms a decent fit.
